

Testing & Quality Assurance (QA) Services

Label: Built Right, Tested Harder

Comprehensive testing that finds issues before your users do, helping you launch reliable software with confidence.

Image Prompt: A focused QA engineer at a dual-monitor desk, one screen showing a test automation dashboard with green and red pass/fail indicators, the other showing code. Clean modern office, soft daylight, navy and orange brand accents, photorealistic.

[TALK TO A QA EXPERT]

Why Quality Assurance Matters

Every bug that reaches a live user costs more than the one caught in development. A checkout button that fails on Safari, an API that times out under real traffic, a form that silently drops data on mobile: these are not small things. They are the moments customers remember, and they decide whether they trust your product again.

Most teams do not lack good developers. They lack a structured way to catch what developers cannot see from inside their own code. That is what QA is for. It is not a formality before launch. It is the process that turns "it works on my machine" into "it works for everyone, every time."

At Deovate, we treat testing as part of how software gets built, not something bolted on at the end. Whether you are shipping a new SaaS platform, an eCommerce store during peak season, or a mobile app update, our QA team validates functionality, performance, security, and usability before your users ever see a problem.

QA Services at a Glance

Service Area | Focus

Manual Testing | Human judgment on real user flows

Automated Testing | Repeatable checks at speed and scale

Functional Testing | Does the feature do what it should

Regression Testing | Nothing breaks when something changes

Performance & Load Testing | How the system behaves under pressure

Security Testing | Where the weak points are before attackers find them

API Testing | Reliability of the connections behind the interface

Cross-Browser Testing | Consistency across Chrome, Firefox, Edge, Safari

Mobile App Testing | Android and iOS behavior across devices

Usability Testing | Whether real users can actually get things done

Accessibility Testing | WCAG compliance for every kind of user

Database Testing | Data integrity from input to storage

Smoke & Sanity Testing | Fast health checks before every release

User Acceptance Testing | Sign-off from the people who matter most, your users

Test Documentation | A record of what was tested and why

QA Consulting | Building testing into how your team already works

1. Manual Testing

Automated scripts are excellent at repeating known checks, but they cannot notice that a page feels confusing or that an error message makes no sense. Manual testing brings a human perspective into the process, someone who explores the product the way a real user would, without a script telling them exactly what to click.

Our testers combine structured test cases with exploratory sessions, deliberately trying to break things, following unexpected paths, and reporting anything that feels off even if it is not technically a bug.

- Exploratory Testing
- Functional Testing
- UI Testing
- User Acceptance Support

Image Prompt: Split-screen image: left side shows a tester's hand clicking through a mobile app UI, right side shows a laptop with a structured test case checklist. Clean, professional, navy/orange accents.

[REQUEST A MANUAL QA AUDIT]

2. Automated Testing

Some things should never be tested by hand more than once. Login flows, payment paths, and core navigation need to be checked every single time you ship code, and doing that manually does not scale. Automated testing turns these repeatable checks into scripts that run in minutes instead of days.

We build automation frameworks around your actual product and release cadence, not a generic template, so the coverage grows with your codebase instead of becoming outdated after the first sprint.

- Test Automation Framework Setup
- Web Automation Testing
- Mobile Automation Testing
- Regression Automation

[AUTOMATE MY TEST SUITE]

3. Functional Testing

Functional testing answers one question directly: does this feature actually do what it was built to do. We validate every requirement against real behavior, checking business logic, workflows, and edge cases that are easy to overlook when a feature is only tested the "happy path" way.

- Feature Validation
- Business Logic Testing
- End-to-End Workflow Testing

- Requirement Verification

[VALIDATE MY FEATURES]

4. Regression Testing

New code fixes one thing and quietly breaks three others. It happens more often than teams like to admit, especially in fast-moving products. Regression testing exists to catch exactly that, confirming that yesterday's working features are still working after today's changes.

- Regression Test Suite
- Feature Impact Analysis
- Release Validation
- Continuous Regression Testing

[PROTECT MY EXISTING FEATURES]

5. Performance & Load Testing

A product that works perfectly for ten users and collapses under ten thousand is not actually ready. Performance and load testing simulates real-world traffic and stress conditions so you know exactly how your system behaves before a sale, a launch, or a viral moment puts it to the real test.

- Load Testing
- Stress Testing
- Scalability Testing
- Performance Optimization Reports

Image Prompt: A server room or cloud dashboard visualization showing a traffic spike graph climbing steadily, with performance metrics overlaid, dark navy UI with orange highlight accents.

[STRESS-TEST MY SYSTEM]

6. Security Testing

Every application collects, stores, or moves data that someone could try to exploit. Security testing looks at your product the way an attacker would, probing authentication, authorization, and common vulnerabilities before they become headlines.

- Vulnerability Assessment
- Authentication Testing
- Authorization Testing
- OWASP Security Checks

[GET A SECURITY ASSESSMENT]

7. API Testing

Most modern products are held together by APIs that users never see directly, but every one of those connections is a potential point of failure. We test the contracts between systems directly, independent of whatever interface sits on top of them.

- REST API Testing

- GraphQL API Testing
- API Automation
- API Performance Testing

[TEST MY APIS]

8. Cross-Browser Testing

A feature that works in Chrome can behave completely differently in Safari. Cross-browser testing confirms your product looks and functions correctly everywhere your customers actually show up, not just in the browser your team happens to use.

- Chrome Testing
- Firefox Testing
- Edge Testing
- Safari Testing

[CHECK MY BROWSER COVERAGE]

9. Mobile App Testing

Android and iOS are different ecosystems with different rules, screen sizes, and user expectations. We test your app across real device and OS combinations so performance and behavior hold up outside the one phone your team uses for development.

- Android Testing
- iOS Testing
- Device Compatibility Testing
- App Performance Testing

[TEST MY MOBILE APP]

10. Usability Testing

A product can be fully functional and still frustrate the people using it. Usability testing looks past whether something technically works and asks whether real users can actually accomplish what they came to do, without confusion or extra effort.

- User Journey Evaluation
- Navigation Testing
- Accessibility Review
- UX Feedback Analysis

[EVALUATE MY USER EXPERIENCE]

11. Accessibility Testing

Accessible software is not a compliance checkbox, it is a wider door for more of your customers to walk through. We test against WCAG standards so people using screen readers, keyboard navigation, or assistive technology can use your product without hitting walls your team never noticed.

- WCAG Compliance Testing
- Keyboard Navigation Testing

- Screen Reader Compatibility
- Color Contrast Verification

[CHECK MY ACCESSIBILITY COMPLIANCE]

12. Database Testing

An interface can look perfect while the data underneath it is quietly corrupted, duplicated, or lost. Database testing verifies that information moves through your system accurately, from the moment a user submits it to however long it needs to be stored.

- Data Integrity Testing
- Database Validation
- SQL Query Verification
- Data Migration Testing

[VALIDATE MY DATA INTEGRITY]

13. Smoke & Sanity Testing

Before a full test cycle even begins, we run fast checks to confirm the build is stable enough to test at all. This saves time on both sides, catching obvious breakages early instead of discovering them halfway through a deep testing pass.

- Build Verification Testing
- Release Readiness Testing
- Quick Health Checks
- Critical Feature Validation

[RUN A PRE-RELEASE CHECK]

14. User Acceptance Testing (UAT)

Technical correctness and business fit are not always the same thing. UAT brings real stakeholders into the process to confirm the product actually solves the problem it was built for, before it goes live to your customers.

- UAT Planning
- Business Scenario Testing
- Client Acceptance Support
- Issue Verification

[PLAN A UAT CYCLE]

15. Test Case Design & Documentation

Good testing needs to be repeatable, not something that lives only in one tester's memory. We document test plans, cases, and scenarios clearly, so your team has a lasting reference and every defect is reported with enough detail to act on immediately.

- Test Plan Creation
- Test Case Writing
- Test Scenario Documentation

- Defect Reporting

[GET A TEST DOCUMENTATION PACKAGE]

16. QA Consulting & Process Improvement

Sometimes the gap is not a missing test, it is a missing process. We assess how your team currently handles quality, then help build testing into your existing workflow and CI/CD pipeline so it strengthens delivery speed instead of slowing it down.

- QA Process Assessment
- Test Strategy Development
- CI/CD Quality Integration
- Quality Metrics & Reporting

[BOOK A QA PROCESS REVIEW]

Our QA Process

1. Discovery: We review your product, requirements, and existing test coverage to understand where the real risk sits.
2. Test Strategy: We define what gets tested manually, what gets automated, and in what order, based on impact.
3. Test Execution: Our team runs structured and exploratory testing across functional, performance, security, and usability layers.
4. Defect Reporting: Every issue is logged with clear reproduction steps, severity, and evidence, not vague notes.
5. Retesting & Regression: Fixes are verified and the surrounding features are re-checked to confirm nothing new broke.
6. Sign-Off & Reporting: You receive a clear quality report before release, so the decision to ship is based on evidence, not hope.

Image Prompt: A simple horizontal process flow diagram with six connected steps, minimal icons, navy line connectors with orange step numbers, clean whitespace, corporate style.

Tools & Technologies We Work With

Automation: Selenium, Playwright, Cypress, Appium

API Testing: Postman, REST Assured, Insomnia

Performance: JMeter, k6, LoadRunner

Security: Burp Suite, OWASP ZAP

Bug Tracking & Docs: Jira, TestRail, Azure DevOps

CI/CD Integration: Jenkins, GitHub Actions, GitLab CI

Why Teams Choose Deovate for QA

We are not a testing team bolted onto someone else's project. We build software ourselves, which means we know exactly where bugs like to hide because we have shipped code under the same

deadlines you are working with.

- Testers who understand both business logic and technical implementation, not just checklists.
- Clear, actionable defect reports your developers can act on the same day.
- Flexible engagement: a one-time audit, ongoing QA support, or embedded team extension.
- Testing built around your release cycle, not a rigid process you have to work around.
- Transparent reporting so you always know your product's real quality status, not just a pass or fail.

Industries We Test For

SaaS Platforms, eCommerce & Marketplaces, FinTech & Payments, Healthcare Software, Logistics & Supply Chain, Education Technology, Enterprise Business Tools, Travel & Hospitality Platforms.

Frequently Asked Questions

Do you offer one-time testing or ongoing QA support?

Both. Some clients need a focused audit before a major release, others bring us in as an ongoing extension of their team across every sprint.

Can you test an existing product, or only new builds?

We regularly take over QA for live products with no existing documentation, and start by mapping the current state before building a test plan around it.

Do you provide automated testing if we already have manual QA in place?

Yes. We often layer automation on top of existing manual processes, automating the repetitive checks so your team can focus on exploratory and usability testing.

How do you report bugs to our development team?

Every defect is logged in the tracking tool you already use, with clear steps to reproduce, screenshots or recordings, and severity so nothing gets lost in translation.

Can QA be integrated into our CI/CD pipeline?

Yes, we set up automated test suites to run on every build, so quality checks happen continuously rather than only right before release.

How quickly can you start?

Most engagements begin within a week of scoping, depending on access to your codebase, environment, and existing documentation.

Ready to Ship With Confidence

Whether you need a one-time audit before a major launch or a QA partner for the long run, we will build a testing approach around your product, not a generic checklist.
